## 14 位,400 每秒百万次采样 (MSPS) 模数转换器

查询样品: ADS5474-SP

## 特性

- 400 MSPS 采样率
- 14 位分辨率, 10.9 位有效位数 (ENOB)
- 1.28GHz 输入带宽
- 230MHz 和 400MSPS 时,无杂散动态范围 (SFDR) = 78dBc
- 230MHz 和 400MSPS 时,信噪比 (SNR) = 69.8dBFS
- 2.2 V<sub>PP</sub>差分输入电压
- 兼容低压差分信令 (LVDS) 的输出
- 总功率耗散: 2.5W
- 断电模式: 50mW
- 偏移二进制输出格式
- 半速率输出时钟上升沿和下降沿的输出数据变换
- 片上模拟缓冲器、跟踪保持和基准电路

- 采用 84 引脚陶瓷绝缘分流条封装 (HFG)
- 军用温度范围:
   -55°C 至 +125°C T<sub>か売</sub>
- 可提供工程评估 (/EM) 样品 (1)
- 与 12 位和 14 位系列引脚相似且兼容: ADS5463-SP 和 ADS5444-SP

## 应用范围

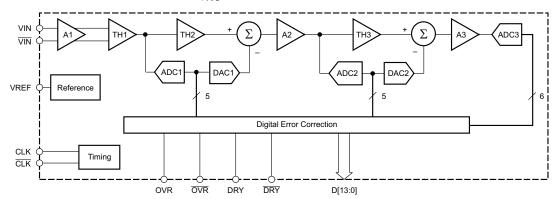

- 测试和测量仪器
- 软件定义无线电
- 数据采集
- 功率放大器线性化
- 通信仪器
- 雷达
- (1) 这些部件只用于工程评估。它们的加工工艺为非兼容流程(例如,无预烧过程等)并且只在 25°C 的温度额定值下测试。 这些部件不适合于品质检定、生产、辐射测试或飞行使用。 不担保完全军用额定温度
  - -55°C 至 125°C 范围内或使用寿命内的部件性能。

## 说明/订购信息

ADS5474 是一款 14 位,400MSPS 模数转换器 (ADC),此转换器在提供 LVDS 兼容数字输出的同时,可由 5V 和 3V 电源供电运行。这个 ADC 是 12,13,14 位 ADC 系列的一员,采样率在 210MSPS 至 500MSPS 之间。ADS5474 输入缓冲器隔离了板上跟踪和保持 (T&H) 的内部开关,这样在提供一个高阻抗输入的同时,防止内部开关干扰信号源。还提供了一个内部基准发生器来简化系统设计。

在采样率为 400MSPS 时,针对超过 400MHz 的宽带宽信号的转换,设计使用 1.4GHz 输入带宽,ADS5474 在宽输入频率范围内具有出色低噪声性能和无杂散动态范围。

ADS5474 采用 84 引脚陶瓷绝缘分流条封装 (HFG)。 此器件采用德州仪器 (TI) 互补双极工艺 (BiCom3) 制造,并且在完全军用温度范围(-55°C 至 +125°C  $T_{\text{外壳}}$ )内额定运行。

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

#### ABSOLUTE MAXIMUM RATINGS(1)

Over operating free-air temperature range, unless otherwise noted.

		ADS5474-SP	UNIT
	AVDD5 to GND	6	V
Supply voltage	AVDD3 to GND	5	V
	DVDD3 to GND	5	V
Analog input to Gl	ND	-0.3 to (AVDD5 + 0.3)	V
Clock input to GN	D	-0.3 to (AVDD5 + 0.3)	V
CLK to CLK		±2.5	V
Digital data output	t to GND	-0.3 to (DVDD3 + 0.3)	V
Operating case te	mperature range, T <sub>C</sub>	-55 to +125	°C
Maximum junction	temperature, T <sub>J</sub>	+150	°C
Storage temperate	ure range	-65 to +150	°C
ESD, human-body	/ model (HBM)	2	kV

<sup>(1)</sup> Stresses above these ratings may cause permanent damage. Exposure to absolute maximum conditions for extended periods may degrade device reliability. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those specified is not implied. Kirkendall voidings and current density information for calculation of expected lifetime are available upon request.

## THERMAL CHARACTERISTICS(1)

PARAMETER		TEST CONDITIONS	TYP	UNIT
$R_{\thetaJA}$	Junction-to-free-air thermal resistance	Junction-to-case thermal resistance	21.81	°C/W
$R_{\thetaJC}$	Junction-to-case thermal resistance	MIL-STD-883 Test Method 1012	0.849	°C/W

(1) This CQFP package has built-in vias that electrically and thermally connect the bottom of the die to a pad on the bottom of the package. To efficiently remove heat and provide a low-impedance ground path, a thermal land is required on the surface of the PCB directly underneath the body of the package. During normal surface mount flow solder operations, the heat pad on the underside of the package is soldered to this thermal land creating an efficient thermal path. Normally, the PCB thermal land has a number of thermal vias within it that provide a thermal path to internal copper areas (or to the opposite side of the PCB) that provide for more efficient heat removal. TI typically recommends an 11,9 mm2 board-mount thermal pad. This allows maximum area for thermal dissipation, while keeping leads away from the pad area to prevent solder bridging. A sufficient quantity of thermal/electrical vias must be included to keep the device within recommended operating conditions. This pad must be electrically at ground potential.

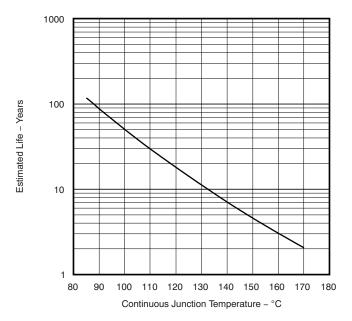

Figure 1. Operating Life Derating Chart, Electromigration Fail Mode

## RECOMMENDED OPERATING CONDITIONS

		MIN	TYP	MAX	UNIT
SUPPLIE	S	<del>-</del>			
AVDD5	Analog supply voltage	4.75	5	5.25	V
AVDD3	Analog supply voltage	3.1	3.3	3.6	V
DVDD3	Output driver supply voltage	3	3.3	3.6	V
ANALOG	INPUT				
	Differential input range		2.2		$V_{PP}$
VCM	Input common mode		3.1		V
DIGITAL	OUTPUT (DRY, DATA, OVR)				
	Maximum differential output load		10		pF

#### TIMING INFORMATION

(1) Polarity of DRY is undetermined. For further information, see the Digital Outputs section.

Figure 2. Timing Diagram

## TIMING CHARACTERISTICS(1)

	PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
ta	Aperture delay			200		ps
	Aperture jitter, rms	Internal jitter of the ADC		103		fs
	Latency			3.5		cycles
t <sub>CLK</sub>	Clock period		2.5		50	ns
t <sub>CLKH</sub>	Clock pulse duration, high		1			ns
t <sub>CLKL</sub>	Clock pulse duration, low		1			ns
t <sub>DRY</sub>	CLK to DRY delay <sup>(2)</sup>	Zero crossing, 10-pF parasitic loading to GND on each output pin	700	1600	2500	ps
t <sub>DATA</sub>	CLK to DATA/OVR delay <sup>(2)</sup>	Zero crossing, 10-pF parasitic loading to GND on each output pin	650	1600	2600	ps
t <sub>SKEW</sub>	DATA to DRY skew	$t_{DATA} - t_{DRY}$ , 10-pF parasitic loading to GND on each output pin	-700	0	700	ps
t <sub>RISE</sub>	DRY/DATA/OVR rise time	10-pF parasitic loading to GND on each output pin		500		ps
t <sub>FALL</sub>	DRY/DATA/OVR fall time	10-pF parasitic loading to GND on each output pin		500		ps

Timing parameters are assured by characterization, but not production tested. DRY, DATA, and OVR are updated on the falling edge of CLK. The latency must be added to  $t_{DATA}$  to determine the overall propagation (2) delay.

#### APPLICATIONS INFORMATION

## **Theory of Operation**

The ADS5474 is a 14-bit, 400-MSPS, monolithic pipeline ADC. Its bipolar analog core operates from 5-V and 3.3-V supplies, while the output uses a 3.3-V supply to provide LVDS-compatible outputs. The conversion process is initiated by the rising edge of the external input clock. At that instant, the differential input signal is captured by the input track-and-hold (T&H), and the input sample is converted sequentially by a series of lower resolution stages, with the outputs combined in a digital correction logic block. Both the rising and the falling clock edges are used to propagate the sample through the pipeline every half clock cycle. This process results in a data latency of 3.5 clock cycles, after which the output data are available as a 14-bit parallel word, coded in offset binary format.

## **Input Configuration**

The analog input for the ADS5474 consists of an analog pseudo-differential buffer followed by a bipolar transistor T&H. The analog buffer isolates the source driving the input of the ADC from any internal switching and presents a high impedance that is easy to drive at high input frequencies, compared to an ADC without a buffered input. The input common-mode is set internally through a 500- $\Omega$  resistor connected from 3.1 V to each of the inputs (common-mode is ~2.4V on 12- and 13-bit members of this family). This configuration results in a differential input impedance of 1 k $\Omega$ .

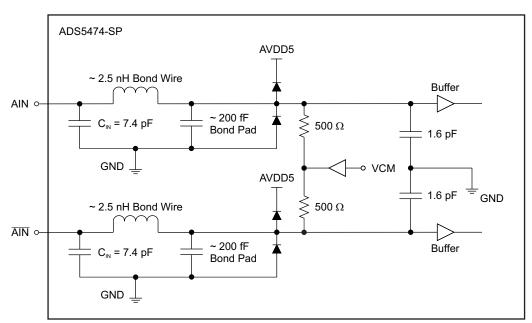

Figure 30. Analog Input Equivalent Circuit

For a full-scale differential input, each of the differential lines of the input signal (pins 16 and 17) swings symmetrically between (3.1 V + 0.55 V) and (3.1 V – 0.55 V). This range means that each input has a maximum signal swing of 1.1  $V_{PP}$  for a total differential input signal swing of 2.2  $V_{PP}$ . Operation below 2.2  $V_{PP}$  is allowable, with the characteristics of performance versus input amplitude demonstrated in Figure 19 and Figure 20. For instance, for performance at 1.1  $V_{PP}$  rather than 2.2  $V_{PP}$ , refer to the SNR and SFDR at –6 dBFS (0 dBFS = 2.2  $V_{PP}$ ). The maximum swing is determined by the internal reference voltage generator, eliminating the need for any external circuitry for this purpose.

The ADS5474 performs optimally when the analog inputs are driven differentially. The circuit in Figure 31 shows one possible configuration using an RF transformer with termination either on the primary or on the secondary of the transformer. In addition, the evaluation module is configured with two back-to-back transformers, also demonstrating good performance. If voltage gain is required, a step-up transformer can be used.

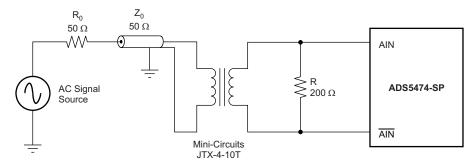

Figure 31. Converting a Single-Ended Input to a Differential Signal Using an RF Transformer

In addition to the transformer configurations, Texas Instruments offers a wide selection of single-ended operational amplifiers that can be selected depending on the application. An RF gain-block amplifier, such as Texas Instruments' THS9001, can also be used for high-input-frequency applications. For large voltage gains at intermediate-frequencies in the 50 MHz to 400 MHz range, the configuration shown in Figure 32 can be used. The component values can be tuned for different intermediate frequencies. The example shown in Figure 32 is located on the evaluation module and is tuned for an IF of 170 MHz. More information regarding this configuration can be found in the ADS5474 EVM User Guide (SLAU194) and the THS9001 50-MHz to 350-MHz Cascadeable Amplifier data sheet (SLOS426), both available for download at www.ti.com.

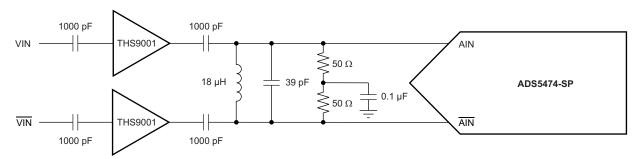

Figure 32. Using the THS9001 IF Amplifier With the ADS5474

For applications requiring dc-coupling with the signal source, a differential input/differential output amplifier such as the THS4509 (shown in Figure 33) provides good harmonic performance and low noise over a wide range of frequencies.

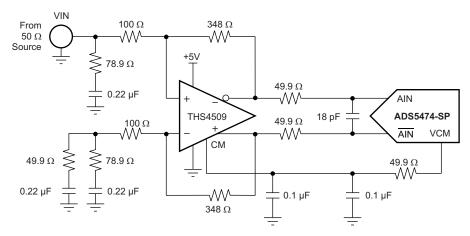

Figure 33. Using the THS4509 or THS4520 With the ADS5474

In this configuration, the THS4509 amplifier circuit provides 10 dB of gain, converts the single-ended input to differential, and sets the proper input common-mode voltage to the ADS5474 by utilizing the VCM output pin of the ADC. The 50-Ω resistors and 18-pF capacitor between the THS4509 outputs and ADS5474 inputs (along with the input capacitance of the ADC) limit the bandwidth of the signal to about 70 MHz (-3 dB). Input termination is accomplished via the 78.9-Ω resistor and 0.22-μF capacitor to ground, in conjunction with the input impedance of the amplifier circuit. A 0.22-μF capacitor and 49.9-Ω resistor are inserted to ground across the 78.9-Ω resistor and 0.22-μF capacitor on the alternate input to balance the circuit. Gain is a function of the source impedance, termination, and 348-Ω feedback resistor. See the THS4509 data sheet for further component values to set proper  $50-\Omega$  termination for other common gains. Because the ADS5474 recommended input common-mode voltage is 3.1 V, the THS4509 operates from a single power-supply input with  $V_{S+} = 5$  V and V<sub>s</sub> = 0 V (ground). This configuration has the potential to slightly exceed the recommended output voltage from the THS4509 of 3.6V due to the ADC input common-mode of 3.1V and the +0.55V full-scale signal. This will not harm the THS4509 but may result in a degradation in the harmonic performance of the THS4509. An amplifier with a wider recommended output voltage range is the THS4520, which is optimized for low noise and low distortion in the range of frequencies up to ~20 MHz. Applications that are not sensitive to harmonic distortion could consider either device at higher frequencies.

#### **Clock Inputs**

The ADS5474 clock input can be driven with either a differential clock signal or a single-ended clock input. The characterization of the ADS5474 is typically performed with a 3- $V_{PP}$  differential clock, but the ADC performs well with a differential clock amplitude down to ~0.5  $V_{PP}$ , as shown in . The clock amplitude becomes more of a factor in performance as the analog input frequency increases. In low-input-frequency applications, where jitter may not be a big concern, the use of a single-ended clock could save cost and board space without much performance tradeoff. When clocked with this configuration, it is best to connect  $\overline{CLK}$  to ground with a 0.01- $\mu$ F capacitor, while CLK is ac-coupled with a 0.01- $\mu$ F capacitor to the clock source, as shown in Figure 35.

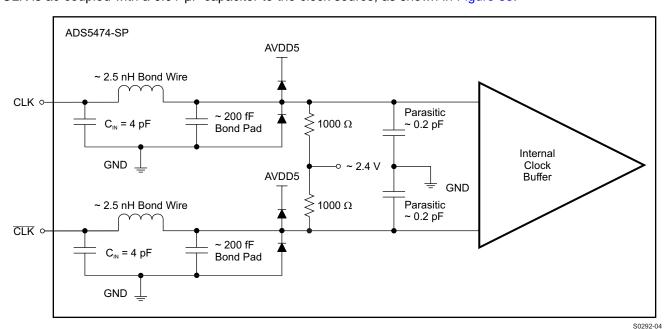

Figure 34. Clock Input Circuit

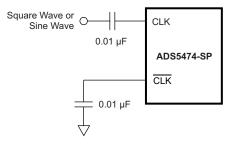

Figure 35. Single-Ended Clock

For jitter-sensitive applications, the use of a differential clock has some advantages at the system level. The differential clock allows for common-mode noise rejection at the printed circuit board (PCB) level. With a differential clock, the signal-to-noise ratio of the ADC is better for jitter-sensitive, high-frequency applications because the board level clock jitter is superior.

Larger clock amplitude levels are recommended for high analog input frequencies or slow clock frequencies. In the case of a sinusoidal clock, larger amplitudes result in higher clock slew rates and reduces the impact of clock noise on jitter. At high analog input frequencies, the sampling process is sensitive to jitter. And at slow clock frequencies, a small amplitude sinusoidal clock has a lower slew rate and can create jitter-related SNR degradation. Figure 36 demonstrates a recommended method for converting a single-ended clock source into a differential clock; it is similar to the configuration found on the evaluation board and was used for much of the characterization. See also *Clocking High Speed Data Converters* (SLYT075) for more details.

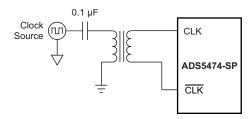

Figure 36. Differential Clock

The common-mode voltage of the clock inputs is set internally to 2.4 V using internal  $1-k\Omega$  resistors. It is recommended to use ac coupling, but if this scheme is not possible, the ADS5474 features good tolerance to clock common-mode variation. Additionally, the internal ADC core uses both edges of the clock for the conversion process. Ideally, a 50% duty-cycle clock signal should be provided.

The ADS5474 is capable of achieving 69.2 dBFS SNR at 350 MHz of analog input frequency. In order to achieve the SNR at 350 MHz the clock source rms jitter must be at least 144 fsec in order for the total rms jitter to be 177 fsec. A summary of maximum recommended rms clock jitter as a function of analog input frequency is provided in Table 2. The equations used to create the table are also presented.

**MAXIMUM CLOCK INPUT FREQUENCY MEASURED SNR TOTAL JITTER** JITTER (MHz) (dBc) (fsec rms) (fsec rms) 30 69.3 1818 1816 70 69.1 798 791 130 69.1 429 417 230 68.8 251 229 350 68.2 177 144 450 67.4 151 110

Table 2. Recommended RMS Clock Jitter

Equation 1 and Equation 2 are used to estimate the required clock source jitter.

65.6

63.7

SNR (dBc) = 
$$-20 \times LOG10 (2 \times \pi \times f_{IN} \times j_{TOTAL})$$

750

1000

$$j_{TOTAL} = (j_{ADC}^2 + j_{CLOCK}^2)^{1/2}$$
(2)

111

104

where:

 $j_{TOTAL}$  = the rms summation of the clock and ADC aperture jitter;

j<sub>ADC</sub> = the ADC internal aperture jitter which is located in the data sheet;

j<sub>CLOCK</sub> = the rms jitter of the clock at the clock input pins to the ADC; and

 $f_{IN}$  = the analog input frequency.

Notice that the SNR is a strong function of the analog input frequency, not the clock frequency. The slope of the clock source edges can have a mild impact on SNR as well and is not taken into account for these estimates. For this reason, maximizing clock source amplitudes at the ADC clock inputs is recommended, though not required (faster slope is desirable for jitter-related SNR). For more information on clocking high-speed ADCs, see Application Note SLWA034, *Implementing a CDC7005 Low Jitter Clock Solution For High-Speed, High-IF ADC Devices*, on the Texas Instruments web site. Recommended clock distribution chips (CDCs) are the TI CDC7005, the CDCM7005-SP and CDCE72010. Depending on the jitter requirements, a band pass filter (BPF) is sometimes required between the CDC and the ADC. If the insertion loss of the BPF causes the clock amplitude to be too low for the ADC, or the clock source amplitude is too low to begin with, an inexpensive amplifier can be placed between the CDC and the BPF.

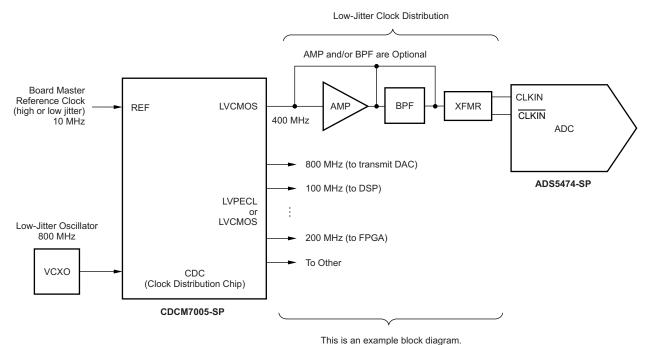

42

14

(1)

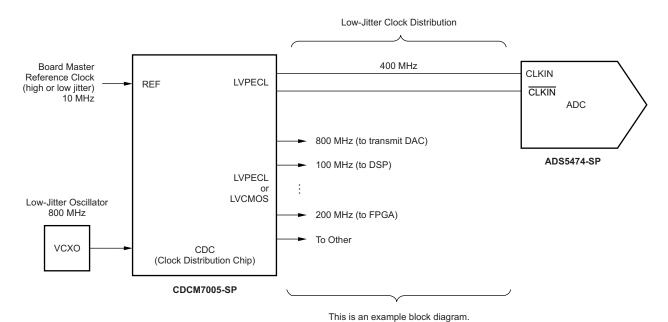

Figure 37 represents a scenario where an LVCMOS single-ended clock output is used from a TI CDCM7005-SP with the clock signal path optimized for maximum amplitude and minimum jitter. This type of conditioning might generally be well-suited for use with greater than 150 MHz of input frequency. The jitter of this setup is difficult to estimate and requires a careful phase noise analysis of the clock path. The BPF (and possibly a low-cost amplifier because of insertion loss in the BPF) can improve the jitter between the CDC and ADC when the jitter provided by the CDC is still not adequate. The total jitter at the CDCM7005-SP output depends largely on the phase noise of the VCXO selected, as well as the CDCM7005-SP, and typically has 50–100 fs of rms jitter. If it is determined that the jitter from the CDCM7005-SP with a VCXO is sufficient without further conditioning, it is possible to clock the ADS5474 directly from the CDCM7005-SP using differential LVPECL outputs, as illustrated in Figure 38 (see the CDCM7005-SP data sheet for the exact schematic). This scenario may be more suitable for less than 150 MHz of input frequency where jitter is not as critical. A careful analysis of the required jitter is recommended before determining the proper approach.

Consult the CDCM7005 data sheet for proper schematic and specifications regarding allowable input and output frequency and amplitude ranges.

Figure 37. Optimum Jitter Clock Circuit

Consult the CDCM7005 data sheet for proper schematic and specifications regarding allowable input and output frequency and amplitude ranges.

Figure 38. Acceptable Jitter Clock Circuit

## **Digital Outputs**

The ADC provides 14 LVDS-compatible, offset binary data outputs (D13 to D0; D13 is the MSB and D0 is the LSB), a data-ready signal (DRY), and an over-range indicator (OVR). It is recommended to use the DRY signal to capture the output data of the ADS5474. DRY is source-synchronous to the DATA/OVR outputs and operates at the same frequency, creating a half-rate DDR interface that updates data on both the rising and falling edges of DRY. It is recommended that the capacitive loading on the digital outputs be minimized. Higher capacitance shortens the data-valid timing window. The values given for timing (see Figure 2) were obtained with a measured 10-pF parasitic board capacitance to ground on each LVDS line (or 5-pF differential parasitic capacitance). When setting the time relationship between DRY and DATA at the receiving device, it is generally recommended that setup time be maximized, but this partially depends on the setup and hold times of the device receiving the digital data (like an FPGA or Field Programmable Field Array). Since DRY and DATA are coincident, it will likely be necessary to delay either DRY or DATA such that setup time is maximized.

Referencing Figure 2, the polarity of DRY with respect to the sample N data output transition is undetermined because of the unknown startup logic level of the clock divider that generates the DRY signal (DRY is a frequency divide-by-two of CLK). Either the rising or the falling edge of DRY will be coincident with sample N and the polarity of DRY could invert when power is cycled off/on or when the power-down pin is cycled. Data capture from the transition and not the polarity of DRY is recommended, but not required. If the synchronization of multiple ADS5474 devices is required, it might be necessary to use a form of the CLKIN signal rather than DRY to capture the data.

The DRY frequency is identical on the ADS5474 and ADS5463 (where DRY equals  $\frac{1}{2}$  the CLK frequency), but different than it is on the pin-similar ADS5444 (where DRY equals the CLK frequency). The LVDS outputs all require an external  $100-\Omega$  load between each output pair in order to meet the expected LVDS voltage levels. For long trace lengths, it may be necessary to place a  $100-\Omega$  load on each digital output as close to the ADS5474 as possible and another  $100-\Omega$  differential load at the end of the LVDS transmission line to provide matched impedance and avoid signal reflections. The effective load in this case reduces the LVDS voltage levels by half.

The OVR output equals a logic high when the 14-bit output word attempts to exceed either all 0s or all 1s. This flag is provided as an indicator that the analog input signal exceeded the full-scale input limit of approximately  $2.2\ V_{PP}$  (± gain error). The OVR indicator is provided for systems that use gain control to keep the analog input signal within acceptable limits.

#### **Power Supplies**

The ADS5474 uses three power supplies. For the analog portion of the design, a 5-V and 3.3-V supply (AVDD5 and AVDD3) are used, while the digital portion uses a 3.3-V supply (DVDD3). The use of low-noise power supplies with adequate decoupling is recommended. Linear supplies are preferred to switched supplies; switched supplies tend to generate more noise components that can be coupled to the ADS5474. The user may be able to supply power to the device with a less-than-ideal supply and still achieve good performance. It is not possible to make a single recommendation for every type of supply and level of decoupling for all systems. The power consumption of the ADS5474 does not change substantially over clock rate or input frequency as a result of the architecture and process.

Because there are two diodes connected in reverse between AVDD3 and DVDD3 internally, a power-up sequence is recommended. When there is a delay in power up between these two supplies, the one that lags could have current sinking through an internal diode before it powers up. The sink current can be large or small depending on the impedance of the external supply and could damage the device or affect the supply source.

The best power up sequence is one of the following options (regardless of when AVDD5 powers up):

- 1) Power up both AVDD3 and DVDD3 at the same time (best scenario), OR
- 2) Keep the voltage difference less than 0.8V between AVDD3 and DVDD3 during the power up (0.8V is not a hard specification a smaller delta between supplies is safer).

If the above sequences are not practical then the sink current from the supply needs to be controlled or protection added externally. The max transient current (on the order of µsec) for DVDD3 or AVDD3 pin is 500mA to avoid potential damage to the device or reduce its lifetime.

Values for analog and clock input given in the Absolute Maximum Ratings are valid when the supplies are on. When the power supplies are off and the clock or analog inputs are still alive, the input voltage and current needs to be limited to avoid device damage. If the ADC supplies are off, the max/min continuous DC voltage is +/- 0.95 V and max DC current is 20 mA for each input pin (clock or analog), relative to ground.

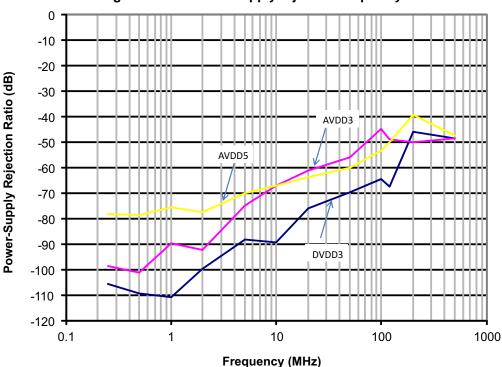

Figure 39. PSRR vs Supply Injected Frequency

#### **DEFINITION OF SPECIFICATIONS**

#### **Analog Bandwidth**

The analog input frequency at which the power of the fundamental is reduced by 3 dB with respect to the low-frequency value.

## **Aperture Delay**

The delay in time between the rising edge of the input sampling clock and the actual time at which the sampling occurs.

## **Aperture Uncertainty (Jitter)**

The sample-to-sample variation in aperture delay.

#### **Clock Pulse Duration/Duty Cycle**

The duty cycle of a clock signal is the ratio of the time the clock signal remains at a logic high (clock pulse duration) to the period of the clock signal, expressed as a percentage.

## **Differential Nonlinearity (DNL)**

An ideal ADC exhibits code transitions at analog input values spaced exactly 1 LSB apart. DNL is the deviation of any single step from this ideal value, measured in units of LSB.

#### Common-Mode Rejection Ratio (CMRR)

CMRR measures the ability to reject signals that are presented to both analog inputs simultaneously. The injected common-mode frequency level is translated into dBFS, the spur in the output FFT is measured in dBFS, and the difference is the CMRR in dB.

## **Effective Number of Bits (ENOB)**

ENOB is a measure in units of bits of converter performance as compared to the theoretical limit based on quantization noise:

$$ENOB = (SINAD - 1.76)/6.02$$
 (3)

#### **Gain Error**

Gain error is the deviation of the ADC actual input full-scale range from its ideal value, given as a percentage of the ideal input full-scale range.

## **Integral Nonlinearity (INL)**

INL is the deviation of the ADC transfer function from a best-fit line determined by a least-squares curve fit of that transfer function. The INL at each analog input value is the difference between the actual transfer function and this best-fit line, measured in units of LSB.

#### **Offset Error**

Offset error is the deviation of output code from midcode when both inputs are tied to common-mode.

## Power-Supply Rejection Ratio (PSRR)

PSRR is a measure of the ability to reject frequencies present on the power supply.

The injected frequency level is translated into dBFS, the spur in the output FFT is measured in dBFS, and the difference is the PSRR in dB. The measurement calibrates out the benefit of the board supply decoupling capacitors.

#### Signal-to-Noise Ratio (SNR)

SNR is the ratio of the power of the fundamental  $(P_S)$  to the noise floor power  $(P_N)$ , excluding the power at dc and in the first five harmonics.

$$SNR = 10log_{10} \frac{P_S}{P_N}$$
 (4)

SNR is either given in units of dBc (dB to carrier) when the absolute power of the fundamental is used as the reference, or dBFS (dB to full-scale) when the power of the fundamental is extrapolated to the converter full-scale range.

#### Signal-to-Noise and Distortion (SINAD)

SINAD is the ratio of the power of the fundamental  $(P_S)$  to the power of all the other spectral components including noise  $(P_N)$  and distortion  $(P_D)$ , but excluding dc.

$$SINAD = 10log_{10} \frac{P_S}{P_N + P_D}$$
 (5)

SINAD is either given in units of dBc (dB to carrier) when the absolute power of the fundamental is used as the reference, or dBFS (dB to full-scale) when the power of the fundamental is extrapolated to the converter full-scale range.

## **Temperature Drift**

Temperature drift (with respect to gain error and offset error) specifies the change from the value at the nominal temperature to the value at  $T_{MIN}$  or  $T_{MAX}$ . It is computed as the maximum variation the parameters over the whole temperature range divided by  $T_{MIN}-T_{MAX}$ .

## **Total Harmonic Distortion (THD)**

THD is the ratio of the power of the fundamental  $(P_S)$  to the power of the first five harmonics  $(P_D)$ .

$$THD = 10log_{10} \frac{P_S}{P_D}$$
 (6)

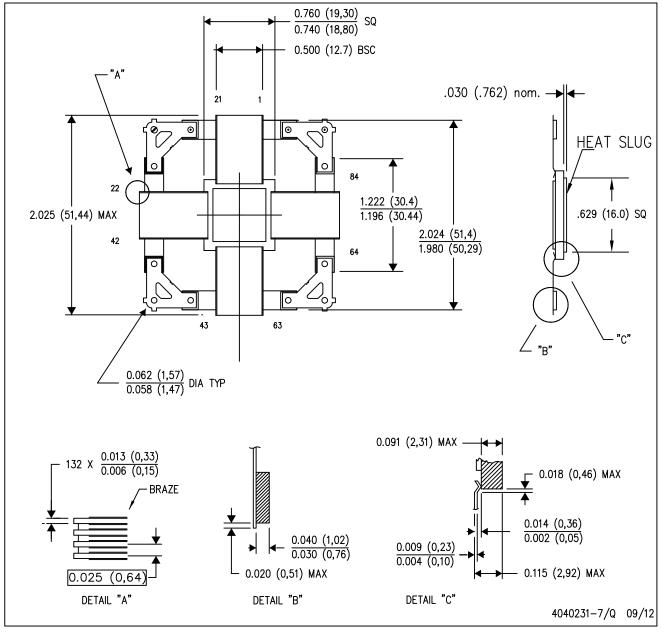

THD is typically given in units of dBc (dB to carrier).

#### Two-Tone Intermodulation Distortion (IMD3)

IMD3 is the ratio of the power of the fundamental (at frequencies  $f_1$ ,  $f_2$ ) to the power of the worst spectral component at either frequency  $2f_1 - f_2$  or  $2f_2 - f_1$ ). IMD3 is given in units of either dBc (dB to carrier) when the absolute power of the fundamental is used as the reference, or dBFS (dB to full-scale) when the power of the fundamental is extrapolated to the converter full-scale range.

## HFG (S-CQFP-F84)

## CERAMIC QUAD FLATPACK WITH NCTB

NOTES:

- A. All linear dimensions are in inches (millimeters).
- B. This drawing is subject to change without notice.
- C. Ceramic quad flatpack with flat leads brazed to non-conductive tie bar carrier.
- D. This package is hermetically sealed with a metal lid.
- E. The leads are gold plated and can be solderdipped.
- F. Leads not shown for clarity purposes.

#### 重要声明

德州仪器(TI) 及其下属子公司有权根据 JESD46 最新标准, 对所提供的产品和服务进行更正、修改、增强、改进或其它更改, 并有权根据 JESD48 最新标准中止提供任何产品和服务。客户在下订单前应获取最新的相关信息, 并验证这些信息是否完整且是最新的。所有产品的销售都遵循在订单确认时所提供的TI 销售条款与条件。

TI 保证其所销售的组件的性能符合产品销售时 TI 半导体产品销售条件与条款的适用规范。仅在 TI 保证的范围内,且 TI 认为 有必要时才会使 用测试或其它质量控制技术。除非适用法律做出了硬性规定,否则没有必要对每种组件的所有参数进行测试。

TI 对应用帮助或客户产品设计不承担任何义务。客户应对其使用 TI 组件的产品和应用自行负责。为尽量减小与客户产品和应 用相关的风险,客户应提供充分的设计与操作安全措施。

TI 不对任何 TI 专利权、版权、屏蔽作品权或其它与使用了 TI 组件或服务的组合设备、机器或流程相关的 TI 知识产权中授予 的直接或隐含权限作出任何保证或解释。TI 所发布的与第三方产品或服务有关的信息,不能构成从 TI 获得使用这些产品或服 务的许可、授权、或认可。使用此类信息可能需要获得第三方的专利权或其它知识产权方面的许可,或是 TI 的专利权或其它 知识产权方面的许可。
